March 20, 2023

Disclaimer

I used a job description from the course when I wrote this project proposal, which is why it was flagged as possibly plagiarized. The possible source directs users to an [Udacity github account](#) that contains the project's starter files. These materials are just the beginning; I'll build on them to complete my endeavor. Additionally, the project's objectives will be the same as those outlined in the starting files.

1 Domain Background

In today world all are becoming online purchase. Here logistics and delivery system play important role. Therefore, the big warehouses require reliable and automated system to sort and distribute packages based on multiple characteristics. In these warehouses, packages/objects are usually carried over in boxes, where each box can hold multiple items. The task for the automated delivery system would be to classify the package and determine where to deliver it. But before that the system needs to know how many packages are in each delivery box and that will be the topic of the proposed Capstone project.

I want to use the [Amazon Bin Image Dataset](#) to measure the number of objects in a box because it contains a picture of the contents of the box and information about other objects, such as how many there are. The adopted solution will determine the number of objects based on this image.

2 Problem Statement

Building the solution for counting number of items in each bin base on a photo of the bin's content. The final model should have known accuracy in order to predict future false detection rate.

3 The datasets and inputs

To complete this project I will be using the [Amazon Bin Image Dataset](#). From this dataset I will make use only of only 10000 images labeled with number of items inside a bin. Dataset will be post-processed and divided into train/valid and test subsets.

Amazon description of the dataset: "The Amazon Bin Image Dataset contains over 500,000 images and metadata from bins of a pod in an operating Amazon Fulfillment Center. The bin images in this dataset are captured as robot units carry pods as part of normal Amazon Fulfillment Center operations."

Selected subset of around 10000 objects will be divided into three subsets for Training, test and validation with ratios 60/20/20% in each set. In the selected dataset number of images per class will be balanced, meaning for each class (number of objects in bin) there will be similar number of test/train/validation images.

4 Solution statement

The final solution is an ML model which will detect the number of items in a box based on the image of the box's content. For the delivered model accuracy will be computed in order to assess the model quality.

5 Benchmark model

As a baseline model I would like to use resnet50 image classification network. ResNet-50 is a convolutional neural network that is 50 layers deep. In AWS cloud there is available a pretrained version of the network trained on more than a million images from the [ImageNet database](#). The pretrained network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the network has learned rich feature representations for a wide range of images. The network has an image input size of 224-by-224.

6 Evaluation Metrics

The quality of the training process will be evaluated using standard metrics: Cross Entropy Loss function and precision(accuracy). These metrics will measure and quantify the solution and ensure its repeatability for further improvements. For the training procedure a hyper parameter optimization might be needed to ensure that the training process will converge to expected result and won't over-fit to the dataset.

7 An outline of the project design

The project will be created in AWS domain using Sagemaker notebooks with some options to limit costs of future development and network training. Main steps to follow in the project consist of:

1. Data preparation
 - fetching data from a database,
 - pre-process data and divide it into test, train and validation subsets
 - upload the data to S3 container
2. Model tuning
 - tune hyperparameters of the model
 - train a machine learning model and observe if there are no anomalies in training.
 - Measure KPI metrics, are their values acceptable for deployment?
3. Model deployment
 - verify that the model is working as expected
 - observe the quality of the outcome object. Decide if the quality is acceptable or the training should be repeated

This project will serve as a demonstration of end-to-end machine learning engineering skills covered in this nanodegree.
